The Smooth Approach to Model Uncertainty and Statistics

The Legacy of Frank Knight

Insurance Premia under Uncertainty

The Smooth Approach to Model Uncertainty and Statistics

• Let $X(\omega) \in \mathbb{R}$ be a financial position

(ロ)、(型)、(E)、(E)、 E) の(の)

- Let $X(\omega) \in \mathbb{R}$ be a financial position
- X is a well-defined contract, ω is an observable state of the world ex post

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

- Let $X(\omega) \in \mathbb{R}$ be a financial position
- X is a well-defined contract, ω is an observable state of the world ex post

 example: digital option, you get 1 \$ if the asset price of Microsoft is above 250

- Let $X(\omega) \in \mathbb{R}$ be a financial position
- X is a well-defined contract, ω is an observable state of the world ex post
- example: digital option, you get 1 \$ if the asset price of Microsoft is above 250
- one likes to write down a probability space, but do we really know P?

Convex Risk Measures

• Aim: Measure risk $\rho(X)$ of a position X in monetary terms

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

• Aim: Measure risk $\rho(X)$ of a position X in monetary terms

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

• for cash
$$m$$
, $\rho(X + m) = \rho(X) - m$

• Aim: Measure risk $\rho(X)$ of a position X in monetary terms

- for cash m, $\rho(X + m) = \rho(X) m$
- monotonicity: if $X \ge Y$, $\rho(X) \le \rho(Y)$

• Aim: Measure risk $\rho(X)$ of a position X in monetary terms

- for cash m, $\rho(X + m) = \rho(X) m$
- monotonicity: if $X \ge Y$, $\rho(X) \le \rho(Y)$
- diversification reduces risk: ρ is convex

Theorem (Föllmer-Schied, Fritelli-Rosazza-Gianin) Convex risk measures have the form

$$\rho(X) = \sup_{Q} E^{Q}[-X] - \alpha(Q)$$

for some penalty functions $\alpha(Q) \in [0, \infty]$ for probability measures Q.

Theorem (Föllmer-Schied, Fritelli-Rosazza-Gianin) Convex risk measures have the form

$$\rho(X) = \sup_{Q} E^{Q}[-X] - \alpha(Q)$$

for some penalty functions $\alpha(Q) \in [0, \infty]$ for probability measures Q.

Corollary (Artzner, Delbaen, Eber, Heath) Positively homogeneous convex risk measures have the form

$$\rho(X) = \sup_{Q \in \mathscr{P}} E^Q[-X]$$

for a set of probability measures \mathcal{P} .

 Risk measures are a way to take model uncertainty into account

- Risk measures are a way to take model uncertainty into account

We work in an ex-ante probability-free setting

AN ECONOMIC PREMIUM PRINCIPLE

HANS BÜHLMANN *

Eidgenössische Technische Hochschule, Zürich

1. PREMIUM CALCULATION PRINCIPLES VERSUS ECONOMIC PREMIUM PRINCIPLES

(a) The notion of premium calculation principle has become fairly generally accepted in the risk theory literature. For completeness we repeat its definition:

A premium calculation principle is a functional \mathfrak{H} assigning to a random variable X (or its distribution function $F_X(x)$) a real number P. In symbols

Ŷ	:	X	\rightarrow	P	
oremium alculation orinciple		random variable		real number	
	or	$F_X(x)$ distribution function	->	P real number	

The interpretation is rather obvious. The random variable X stands for the possible claims of a risk whereas P is the premium charged for assuming this risk.

This is of course formalizing the way actuaries think about premiums. In actuarial terms, the premium is a property of the risk (and nothing else), e.g.

> $\mathfrak{H}[X] = E[X] + \alpha \sigma[X]$ $\mathfrak{H}[X] = (1 + \lambda) E[X], \text{ etc.}$

(b) Of course, in *economics* premiums are not only depending on the risk but also on *market conditions*. Let us assume for a moment that we can describe the risk by a random variable X (as under a)), describe the market conditions by a random variable Z.

Then we want to show how an economic premium principle

 \mathfrak{E} : $(X, Z) \rightarrow P$ pair of real number random variables

 This paper is greatly influenced by an exchange of ideas with Flavio Pressaco. I am also indebted to Hans Gerber for stimulating discussions on this subject.

Definition

We say that a map $H: C \to \mathbb{R}$ is a *premium principle* if

- H(X + m) = H(X) + m for all $X \in C$ and $m \in \mathbb{R}$.
- $H(X) \ge H(0) = 0$ for all $X \in C$ with $X \ge 0$.

Some comments:

The definition of a premium principle implies that H(m) = m, for all m ∈ ℝ, leading to the common assumption of no unjustified risk loading.

► The condition H(X) ≥ 0, for all X ∈ C with X ≥ 0, is a minimal requirement for a sensible notion of a premium principle. A map $R: B_b \to \mathbb{R}$ is called a risk measure

- ▶ R(0) = 0 and R(X + m) = R(X) + m for all $X \in B_b$ and $m \in \mathbb{R}$, note the sign change!
- $R(X) \leq R(Y)$ for all $X, Y \in B_b$ with $X \geq Y$.

A deviation measure (cf. Rockafellar-Uryasev (2013)) is a map $D: C \to \mathbb{R}$ with

- D(X + m) = D(X) for all $X \in C$ and $m \in \mathbb{R}$,
- $D(X) \ge D(0) = 0$ for all $X \in C$.

A map $H: C \to \mathbb{R}$ is a premium principle if and only if

$$H(X) = R(X) + D(X)$$
 for all $X \in C$,

where $R \colon B_b \to \mathbb{R}$ is a risk measure and $D \colon C \to \mathbb{R}$ is a deviation measure.

A map $H \colon C \to \mathbb{R}$ is a premium principle if and only if

$$H(X) = R(X) + D(X)$$
 for all $X \in C$,

where $R \colon B_b \to \mathbb{R}$ is a risk measure and $D \colon C \to \mathbb{R}$ is a deviation measure.

- Monetary measure generalizes expected loss
- deviation measure generalizes variance or other measures of fluctuation

The decomposition needs not be unique

Theorem Let $H: C \to \mathbb{R}$ be a premium principle. Define

$$egin{aligned} &R_{ ext{Max}}(X) := \inf ig\{ H(X_0) \, \big| \, X_0 \in C, \, X_0 \geq X ig\}, \ &D_{ ext{Min}}(X) := H(X) - R_{ ext{Max}}(X). \end{aligned}$$

Then, R_{\max} : $B_b \to \mathbb{R}$ is a risk measure, D_{\min} : $C \to \mathbb{R}$ is a deviation measure.

For every other decomposition of the form H(X) = R(X) + D(X)with a risk measure R and a deviation measure D, we have $R \le R_{\text{Max}}$ and $D \ge D_{\text{Min}}$.

Example: variance principle

Consider the variance principle

$$H(X) = \mathbb{E}_{\mathbb{P}}(X) + rac{ heta}{2} \mathrm{var}_{\mathbb{P}}(X), \quad ext{for } X \in \mathrm{B}_{b},$$

with a constant $\theta \geq 0$.

- Here, R(X) = E_P(X), and D(X) = ^θ/₂var_P(X) is one possible decomposition of H into risk and deviation.
- However, for θ > 0, this is not the "maximal" decomposition.
 For θ > 0, the maximal risk measure R_{Max} is given by

$$R_{\mathrm{Max}}(X) = \max_{\mathbb{Q}\in\mathscr{P}} \mathbb{E}_{\mathbb{Q}}(X) - rac{1}{2 heta} G(\mathbb{Q}|\mathbb{P}),$$

where \mathscr{P} consists of all probability measures \mathbb{Q} , which are absolutely continuous w.r.t. \mathbb{P} and satisfy

$$\mathcal{G}(\mathbb{Q}|\mathbb{P}):=\mathrm{var}_{\mathbb{P}}igg(rac{\mathrm{d}\mathbb{Q}}{\mathrm{d}\mathbb{P}}igg)<\infty.$$

The map G is the Gini concentration index, see Maccheroni et al. (2006,2009).

Example: Economic Premium Principle

Bühlmann (1980) provides a competitive market foundation for insurance premia. In an expected utility framework for a common prior \mathbb{P} , in equilibrium, we have

$$H(X) = rac{\mathbb{E}_{\mathbb{P}}(X\ell'(Z))}{\mathbb{E}_{\mathbb{P}}(\ell'(Z))}$$

for the insurer's loss function ℓ and aggregate endowment Z. Deprez and Gerber (1985) consider convex premium principles. Utility indifference leads to

$$\mathbb{E}_{\mathbb{P}}(\ell(Z+X-p)) = \mathbb{E}_{\mathbb{P}}(\ell(Z)).$$

For constant risk aversion

$$H(X) = rac{1}{lpha} \log rac{\mathbb{E}_{\mathbb{P}} ig(e^{lpha (Z+X)} ig)}{\mathbb{E}_{\mathbb{P}} ig(e^{lpha Z} ig)}, \quad ext{for } X \in \mathrm{B}_b.$$

Wang, Young, and Panjer (1997) derive an axiomatic characterization of premium principles in a competitive market setting that results in a representation using Choquet integrals

$$H(X) = \int_{\min X}^{\infty} g(\mathbb{P}_X(t)) \, \mathrm{d}t + \min X,$$

where, for $t \ge 0$, $\mathbb{P}_X(t) := \mathbb{P}(X > t)$, and g is a suitable distortion function.

Let H be sublinear.

- Suppose that insurance companies trade in an arbitrage-free financial market given by a linear subspace M ⊂ C and a nonnegative linear pricing functional F : M → ℝ with F(1) = 1
- \mathbb{P} is a martingale measure if $\mathbb{E}_{\mathbb{P}}(X) = F(X)$ for $X \in M$
- we need to have H = F on M (competition, arbitrage)
- let R_* be the superhedging functional of the financial market

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

The following statements are equivalent:

- 1. The maximal risk measure in the decomposition of H is the superhedging functional, i.e. $R_{Max} = R_*$.
- 2. A model \mathbb{P} is plausible if and only if it is a martingale measure.

Climate Change is Model Uncertainty

- Weather is the current state of temperature, humidity, pressure, rainfall etc at a given location
- Climate is the probability distribution of weather at a given location
- Climate change induces Knightian uncertainty as the change of probabilities is not deterministic

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Oslo Temperature Distribution Winter

Climate Change Vulnerability Analysis for Oslo

Oslo

INCREASED PROBABILITY

POTENTIALLY INCREASED PROBABILITY

UNCHANGED OR LESS PROBABILITY

UNCERTAIN

These climate changes will create more frequent and more severe climate-related bazards due to more extreme weather and to changes in normal weather. While some of the capital s future climate-related hazards will be acute, others will emerge more gradually. The most acute hazards will be associated with more extreme precipitation. The increases in precipitation that have occurred and that will continue to occur in Oslo will materialise in the form of heavy and intense rainfall. As a consequence, today/s extreme precipitation may become the new normal. This would increase the likelihood of:

- Stormwater and urban floods. We must reduce the extent of impermeable surfaces in the city, manage stormwater locally, and use it as a resource in the urban landscape
- River floods. It will be increasingly important to control where water runs when rivers flood, and to secure flood zones along rivers and streams that take a changed climate into account.
- Landslides and avalanches. Soil deposits and terrain types usually determine where landslides and avalanches occur, and potential slide zones will remain mostly the same, but because they are often triggered by extreme precipitation, future landslides and avalanches in Oslo may become more frequent and cause more damage. This will apply particularly to minor landslides and flood-related debris flows, but also to quick clay slides.
Economics of Climate Change: Uncertainty

Michael Barnett, Climate Change and Uncertainty: An Asset Pricing Perspective, Management Science, to appear

(a) Source: NASA-GISS, NOAA.

A Parametric Statistical Model

- Let θ ∈ Θ = [0, 5] (or ℝ) parametrize the change of average temperature in the next 30 years.
- ► Let P⁰ = N(-2.3, 4) be the temperature distribution in Oslo in February. Climate change uncertainty can then be modeled by the family

$$\mathscr{P} = \left(\mathsf{P}^{\theta} \right)_{\theta \in \Theta}$$

- The different levels of plausibility can be captured by a prior probability μ on Θ.
- How shall we evaluate the outcome of various policies?

The Predictive Probability

The Predictive Probability

 Let X(ω) be the outcome of a policy after 30 years (GDP, Employment, Health, ...)

what is the equivalent insurance premium under risk resp uncertainty?

Lemma

The equivalent premium under risk is

$$f^{\theta} = \theta + a\sigma^2/2.$$

The equivalent premium under uncertainty is

$$f = m + a\sigma^2/2 + bv^2/2.$$

Model uncertainty leads to an additional insurance premium.

Definition

A statistical model $(\Omega, \mathscr{F}, cP = (P^{\theta})_{\theta \in \Theta})$ is identifiable if there exist a measurable function $k : \Omega \to \Theta$ with $P^{\theta}[k = \theta] = 1$ for all $\theta \in \Theta$.

Ellsberg Experiment

Ellsberg's Thought Experiment 1

Ellsberg Urn

- An urn contains 100 blue and red balls in unknown proportions
- composition of the urn is verifiable ex post
- $\omega = (c(olor), n(umberofredballs))$
- P_n : the urn contains *n* red balls

•
$$k(\omega) = P_n$$

Predictive Representation

Theorem (Denti, Pomatto 2022)

If the statistical model $(\Omega, \mathscr{F}, cP = (P^{\theta})_{\theta \in \Theta})$ is identifiable by k, then the smooth utility function has the predictive representation

$$U(X) = \mathbb{E}^{\bar{P}}\left[\phi\left(\mathbb{E}^{\bar{P}}\left[u(X)|k\right]\right)\right].$$

Remark

- Foundation for decision making under uncertainty in identifiable models
- $\sigma(k)$ is the σ -field of pure model uncertainty
- under identifiability, markets might insure such uncertainty and resolve issued with market incompleteness due to Knightian uncertainty (Friday!!)
